# Statistics

---

# Description

---

- ▶ There is a wall with some holes.
- ▶ A socket = 6 holes are in a particular arrangement
- ▶ How many sockets are there in the wall?

- ▶ Size of wall =  $W \times H$
- ▶ Number of holes =  $N$
- ▶ Socket (Figure 3) can be rotated

# Sample

---

*Figure 1*

*Figure 2*

*Figure 3*

# Question

---

- ▶ What is the output of the following wall?

- ▶ What about a 40000 x 40000 wall with all four 100x100 corners filled with holes?
  - ▶ i.e. hole if and only if  
 $x=1..100, 39901..40000$  and  $y=1..100, 39901..40000$
  - ▶ Total: 40000 holes

# Constraints

---

- ▶ In test cases worth 30% of the total points
  - ▶  $1 \leq W, H \leq 1000$  ,  $6 \leq N \leq 1000$  , only upright
- ▶ In test cases worth 50% of the total points
  - ▶  $1 \leq W, H \leq 1000$  ,  $6 \leq N \leq 1000$
- ▶ In test cases worth 70% of the total points
  - ▶  $1 \leq W, H \leq 40000$  ,  $6 \leq N \leq 2000$
- ▶ In all test cases
  - ▶  $1 \leq W, H \leq 40000$  ,  $6 \leq N \leq 50000$
  
- ▶ It is worth noting that  $N \ll WH$

# Solution

---

- ▶ 50%
  - ▶ Runtime:  $O(WH)$
  - ▶ Memory:  $O(WH)$

# 50% Solution

---

- ▶ Create a  $W \times H$  array
- ▶ Fill array with 0
- ▶ For each hole, mark as 1, and then check if this hole can form a socket
  - ▶ Each hole can be checked in constant time
  - ▶ More explained later

# Solution

---

- ▶ 50%

- ▶ Runtime:  $O(WH)$
- ▶ Memory:  $O(WH)$

- ▶ 70%

- ▶ Runtime:  $O(N*N)$
- ▶ Memory:  $O(N)$

# 70%

---

- ▶ Just store the input as-is in an array
- ▶ For each hole, try 4 different directions by linear searching the array.
- ▶ Best case: 4 searches (1 search / direction)
- ▶ Worst case: 20 searches (5 searches / direction)
  
- ▶ Quite easy to implement

# Solution

---

- ▶ 50%

- ▶ Runtime:  $O(WH)$
- ▶ Memory:  $O(WH)$

- ▶ 70%

- ▶ Runtime:  $O(N^2)$
- ▶ Memory:  $O(N)$

- ▶ 100%

- ▶ Runtime:  $O(N \lg N)$
- ▶ Memory:  $O(N)$

# 100%: Binary search

---

- ▶ Change 70% linear search into binary search
- ▶ You can either:
  - ▶ Change the if statement into

```
if (x == xx && y == yy) {  
...  
} else if (x < xx || (y == yy && y < yy)) {  
...  
} else {  
...  
}
```
  - ▶ Use a numeric search key
    - ▶  $\text{Key} = 41000x + y$
    - ▶  $41000 \times 40000 + 40000 = 1640040000 < 2147483647$

# Note

---

- ▶ If you choose 41000, range checking can be skipped
- ▶ You should NOT use 40000 if you don't perform range checking
  - ▶ Otherwise you will be wrapping the wall into a cone
  - ▶ Example:  $(100, -4) == (99, 39996)$

# Wait....

---

- ▶ Since HKOI has no memory limit
- ▶ Can't I just use a very large array?
  - ▶ e.g. `char a[40000][40000];`

## ▶ Questions

1. Does the system allow you to allocate 1.6GB memory?
2. If yes, how much time will it take?
3. Also, how much time required to initialize the array?
4. How much time required to check the holes?

# Want to know the details?

---

- ▶ Attend "Miscellaneous CS Topics"
  - ▶ Computer architecture
  - ▶ Operating system
  - ▶ Programming languages
  - ▶ Software development
