## Promotion Period Solution <br> ALEX POON

## What is Promotion Period

- Promotion Period (Pro P) is a term commonly used in university.
- In university, Pro P represents the promotion period of committees.
- In CUHK, committee members usually "dem beat" during Promotion period.

## Problem Statement

- Snow white has "R" red apples and "G" green apples initially
- There is one seed in every apples
- "w" red seeds + "x" green seeds can trade a red apple
- "y" red seeds + "z" green seeds can trade a green apple
- Eating a red apple increase "P" happiness
- Eating a green apple increase "Q" happiness
- Maximize the happiness

## Sample input

64311326

## Sample output

46

| Red Apple | Green Apple | Red Seed | Green Seed | Thtal Happiness | Action |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 6 | 4 | 0 | 0 | 0 | Initial |
| 0 | 0 | 6 | 4 | 36 | Eat all apples she has |
| 1 | 0 | 3 | 3 | 36 | Trade for a red apple |
| 0 | 0 | 4 | 3 | 38 | Eat a red apple |
| 0 | 1 | 3 | 0 | 38 | Trade for a green apple |
| 0 | 0 | 3 | 1 | 44 | Eat a green apple |
| 1 | 0 | 0 | 0 | 44 | Trade for a red apple |
| 0 | 0 | 1 | 0 | 46 | Eat a red apple |

| Subtask | Max Points | $R, G, W, X, Y, Z$ | $P, Q$ |
| :---: | :---: | :--- | :--- |
| 1 | 40 | $1 \leq R, G, W, X, Y, Z \leq 10$ | $1 \leq P, Q \leq 500$ |
| 2 | 25 | $1 \leq R, G, W, X, Y, Z \leq 3000$ | $1 \leq P, Q \leq 500$ |
| 3 | 35 | $1 \leq R, G, W, X, Y, Z \leq 10^{6}$ | $1 \leq P, Q \leq 500$ |

## Statistic

## Solution 1

- Exhaust all trading permutation
- Let $f(R, G)$ is the maximum happiness can be achieved having $R$ red apples and $G$ green apples
- If we trade a red apple first, the maximum happiness will be $f(R-W+1, G-X)+P$
- If we trade a green apple, the maximum happiness will be $f(R-Y, G-Z+1)+Q$
- Which mean, the maximum happiness $=$
- $\operatorname{Max}(\mathrm{f}(\mathrm{R}-\mathrm{W}+1, \mathrm{G}-\mathrm{X})+\mathrm{P}, \mathrm{f}(\mathrm{R}-\mathrm{Y}, \mathrm{G}-\mathrm{Z}+1)+\mathrm{Q})$

## Solution 1

|  |  |  |
| :--- | :--- | :--- |
|  | $F[4,3]$ |  |
|  |  | $F[1,3]$ |
| $F[6,4]$ |  |  |
|  |  | $F[1,3]$ |
|  | $F[5,2]$ |  |
|  |  | Invalid |
|  |  |  |
|  |  |  |

## Solution 1

- We need to call the function for how many times?
- As W, X, Y, Z >= 1
- We need at least 2 seeds to trade an apple
- Remember we will get 1 seed after trading an apple
- So each time we trade an apple, the total number of seeds will decrease at least 1
- So we can trade at most R + G-1 times (Why -1??)

## Solution 1

- The maximum length of a trading permutation is $\mathrm{R}+$ G-1 as well
- The time complexity of the solution :
- $\mathrm{O}\left(2^{\wedge}(\mathrm{R}+\mathrm{G}-1)\right)$
- Expected score : 40

## Solution 2

- Note that on solution 1
- We call the function $f$ with the same parameter for many times
- $F[1,3]$ is calculated for twice

|  |  |  |
| :---: | :---: | :---: |
|  | $F[4,3]$ |  |
| $F[6,2,2]$ |  |  |
|  |  | $F[1,3]$ |
|  |  | $F[1,3]$ |
|  | $F[5,2]$ |  |
|  |  | Invalid |
|  |  |  |
|  |  |  |

## Solution 2

- Why not memorize all of them so that we need not to call as many times as before

## Solution 2

- How to memorize?
- Use an array
- If $\operatorname{ANS}[R-W+1, G-X]$ is not calc then calc $f(R-W+1, G-X)$ else return $\operatorname{ANS}[\mathrm{R}-\mathrm{W}+1, \mathrm{G}-\mathrm{X}]$
- What is the number of different states?

## Solution 2

- The problem we need to find is $f(R, G)$
- Recall the formula:
- $\operatorname{Max}(\mathrm{f}(\mathrm{R}-\mathrm{W}+1, \mathrm{G}-\mathrm{X})+\mathrm{P}, \mathrm{f}(\mathrm{R}-\mathrm{Y}, \mathrm{G}-\mathrm{Z}+1)+\mathrm{Q})$
- R and G is decreasing
- So there are at most R * G state
- So we need to call the function " f " for at most R * G times but not $2^{\wedge}(R+G-1)$ times

## Solution 2

- Time complexity?
- There is at most R * G states
- We can calculate $f(i, j)$ in $O(1)$
- So, the time complexity : $\mathrm{O}\left(\mathrm{R}^{*} \mathrm{G}\right)$
- Expected score : 65-75

## Solution 3

- We may first analyze the sequence of trading apples
- If we fix the number of red and green apples we trade
- E.G. 4 red apples and 3 green apples
- Does the order of trading affect the result?

## Solution 3

- Example :
- RRRGGGR and RGRGRGR
- Are they the same??
- They can achieve the same happiness :
- $4^{*} \mathrm{P}+3$ * $\mathrm{Q}+$ original
- But, the feasibility of them may be different

## Solution 3

- For example : the sample input
- 64311326
- RGR is feasible
- RRG is not feasible
- So, the order of trading the apples is important, right?
- We need to exhaust all order of trading, right?

## Solution 3

- Yes, it is important, but we don't need to exhaust all order!!!!
- The fact is: If a combination is not feasible in both RRRRRGGGGG and GGGGGRRRRR (Trade all Red apples first or vice versa)
- Then the combination is not feasible in any order!!!!!
- Why??

## Solution 3

- Recall our observation first :
- Observation : Each time we trade an apple, the total number of seeds will decrease at least 1
- Moreover, the numbers of both kind of seeds will not increase when we trade an apple. (Maybe decrease or remain unchange)

## Solution

- RGGGRRGGGR
- 133
- Therefore, If we can trade the 4th red apple, we can trade the $1^{\text {st }}, 2^{\text {nd }}, 3^{\text {rd }}$, red apple before as well
- First assume the last unit of red apple can be trade, then why not put all green apple transaction at the front to maximize the opportunity to complete the trade

## Solution 3

- RGGGRRGGGR -> GGGGGGRRRR
- As the numbers of both kinds of seeds are more at first, so putting G at front can increase the possibility to complete the trade
- Undoubtedly, we should also assume the last unit we trade is a green apple as well

## Solution 3

- We can only exhaust the numbers of red apple and green apple we trade and calculate is it feasible.
- How to calculate?
- RRRRRGGGGG
- We can only calculate if the last $G$ and last $R$ can be traded due to the observation above
- So, we can find the number of seeds we use and we get before trading the last $G / R$ in order to check the feasibility

## Solution 3

- RRRRRGGGGG
- Number of red seeds we need before the last red apple $=W^{*} 4$
- Number of red seeds we get = 4
- Number of green seeds we need $=X^{*} 4$
- Number of green seed we get $=0$
- If $\left(\mathrm{R}+4-\left(\mathrm{W}^{*} 4\right)-\mathrm{W}>=0\right)$ and $\left(\mathrm{G}+\mathrm{o}-\mathrm{X}^{*} 4-\mathrm{X}\right.$ $>=0$ )
- It is feasible
- Don't forget to check the last green apple as well

## Solution 3

- Time complexity :
- The Max. time of red apple and green apple we trade $=2$ * $\mathrm{R} / 2^{*} \mathrm{G}$
- Time complexity $=\mathrm{O}\left(\mathrm{R}^{*} \mathrm{G}\right)$
- Score : 65

## Solution 4

- We can further improve solution 3
- After we exhaust the number of red apples we trade
- We can calculate the number of green apples directly instead of exhausting it

## Solution 4

- E.g. the remaining red seeds and green seeds after trading "i" red apples is 6 and 3 where $\mathrm{Y}=2$ and $\mathrm{Z}=$ 2
- We can directly calculate we can at most trade 2 green apples by :
- $6 / 2=3$
- $3 /(2-1)-(3 \bmod (2-1)=0)=2$
- $\operatorname{Min}(3,2)=2$

## Solution 4

- Therefore, the algorithm becomes :
- Exhaust the red apples we trade: O(R)
- For each number of red apples, calculate the maximum number of green apples we can trade by the remaining seeds: $O(1)$
- Do the same thing again but exhaust the green apples this time: $\mathrm{O}(\mathrm{G})$ * $\mathrm{O}(1)$
- Total time complexity $\mathrm{O}(\max (\mathrm{R}, \mathrm{G}))$
- Expected Score : 100
- Any Question??
