# Binary-indexed Tree

- ▷ Problem:
- ▷ Point update(pos, val)
- ▷ Range query(L, R)

# Binary-indexed Tree

- ▷ Problem:
- ▷ Point update(pos, val)
- ▷ Range query(L, R)

Solution 1: Brute force  
 $O(N^2)$

# Binary-indexed Tree

- ▷ Problem:
- ▷ Point update(pos, val)
- ▷ Range query(L, R)

Solution 2: Segment tree

$O(N \lg N)$

Drawback?

# Binary-indexed Tree

- ▷ Problem:
- ▷ Point update(pos, val)
- ▷ Range query(L, R)

## Drawbacks of segment tree:

- ▷ Hidden constant (4x!)
- ▷ Large memory consumption (2x!)  
Getting serious if you consider  
2-D version...

# Binary-indexed Tree

Consider  $L = 1$  for each  $\text{Query}(L, R)$

That means we consider only  
 $\text{Query}(1, R)$

Idea: break the segment  $[1..R]$  into  
subsegments, lengths having power of  
2

# Binary-indexed Tree

E.g.

$$R = 10$$

$$[1..R] = [1..8] + [9..10]$$
$$2^3 \quad 2^1$$

$$R = 14$$

$$[1..R] = [1..8] + [9..12] + [13..14]$$
$$2^3 \quad 2^2 \quad 2^1$$

Notice that each time we take the greatest power of 2 we can take

# Binary-indexed Tree

Same idea:

For  $R = 10 = 1010$ (binary),

equals

$[1001..1010]$  and  $[0001...1000]$

For  $R = 14 = 1110$ (binary)

equals

$[1101..1110]$  and  $[1001...1100]$  and  
 $[0001..1000]$

# Binary-indexed Tree

- ▷ For query  $[1..R]$ ,
- ▷ Let  $\text{lowbit}(R)$  be the lowest significant '1' bit in  $R$
- ▷ Then  $\text{query}[1..R] = a[R - \text{lowbit}(R) + 1..R] + \text{query}[1..R - \text{lowbit}(R)]$
- ▷  $a[R - \text{lowbit}(R) + 1..R]$  aka  $a[R]$

# Binary-indexed Tree

- ▷ Update (pos, val):
- ▷ while (pos  $\leq$  n)
  - $A[\text{pos}] += \text{val}$
  - $\text{Pos} += \text{lowbit}(\text{pos})$

# Binary-indexed Tree

- ▷ How to implement  $\text{lowbit}(x)$ ?
  - $\text{lowbit}(x) = x \& -x$
- ▷ How to handle  $L \neq 1$ ?
  - $\text{Query}(L, R) = \text{Query}(1, R) - \text{Query}(1, L - 1)$
- ▷ Complexity:
- ▷  $O(N)$  build,  $O(\lg N)$  per query,  $O(N)$  memory
  - Notice constant difference!

# Binary-indexed Tree

BIT usage: when the queries are subtractive

$$\text{i.e. } F(L, R) = F(1, R) - F(1, L - 1)$$

E.g. addition, xor

Segment tree usage: when the queries are additive

$$\text{i.e. } F(L, R) = F(L, M) + F(M + 1, R)$$

E.g. max, min

# Agenda

**Binary-indexed Tree (BIT)**

**Sparse Table**

AVL tree

Treap

# Sparse Table

- ▷ Offline solution to range query problems
- ▷ Offers  $O(1)$  per query
- ▷ after  $O(N \lg N)$  precompute

# Sparse Table

- ▷ Idea similar to BIT
- ▷ What if we maintain, for each position  $i$  and each integer  $k$ , the answer for  $[i..i+2^k-1]$ ?
- ▷ Notice: update now costs  **$O(N)$** !!!

# Sparse Table

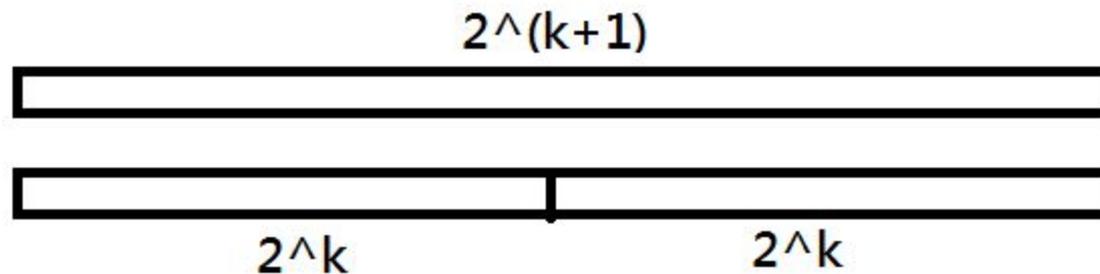

- ▷ Consider range max query (L, R)
  - ▷ If  $2^k \leq (R - L + 1)$ , then
  - ▷ Query(L, L +  $2^k - 1$ ) and
  - ▷ Query(R -  $2^k + 1$ , R) does not exceed the query range
- 
- ▷ But if k is the largest k, these two ranges cover the whole query (L,R)

# Sparse Table

- ▷ Since we have, for all index and all  $k$ , the answer for  $[x..2^{k+1}]$
- ▷ We can just lookup the value of two ranges and max them
  - $O(1)$

# Sparse Table

- ▷ Construction:

- ▷ Combine two  $2^k$  segments to get one  $2^{(k+1)}$  segments!

# Agenda

**Binary-indexed Tree (BIT)**

**Sparse Table**

**AVL tree**

Treap

# AVL Tree

- ▷ Self-balancing binary search tree
- ▷ But wait why do we need one?

# Bad thing about BSTs

- ▷ Let the height of the tree be  $h$
- ▷ For naive implementation of BSTs
  - $h$  is in  $O(n)$
  - Which means every search is  $O(n)$
  - Not much better than brute force scan
- ▷ Target: make BST balanced, by
  - Making  $h$  in  $O(\lg N)$  OR
  - Make the operation fast in amortized time

# Standard tools

- ▷ Normally you want `std::set<int>` to do that
  - Don't even think about coding balanced tree if you can use them
- ▷ Problem: C++ (pre 11) `set` (and `maps`) does not support rank (given an element find out how many elements are larger than itself)

# AVL

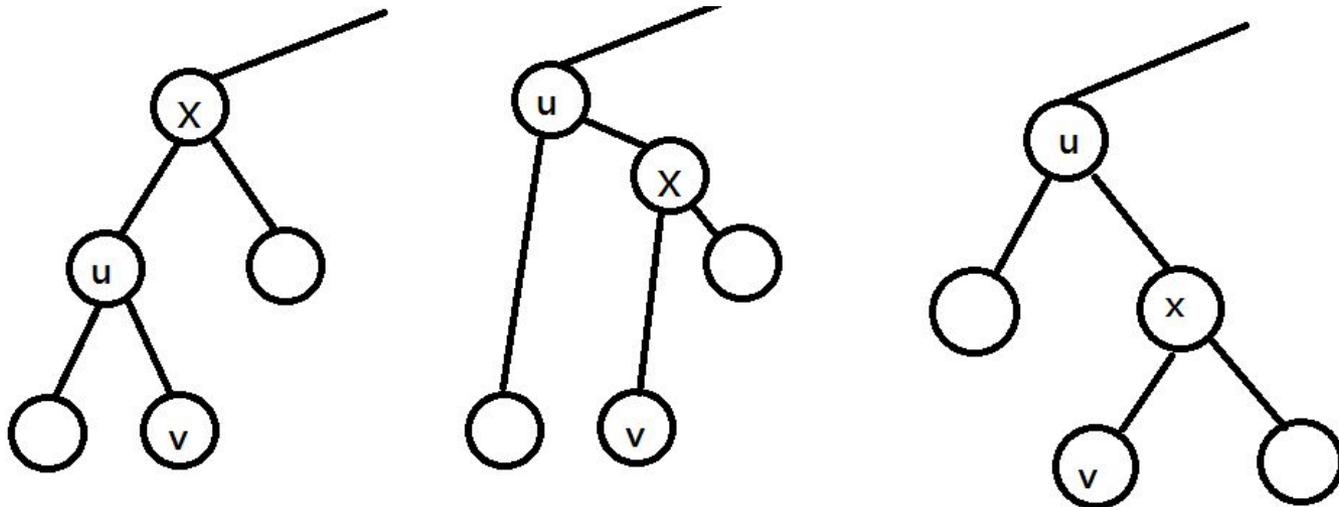

- ▷ **Former approach**
  - Make the tree very balanced when
    - Insert OR
    - Delete
  - And make queries very fast

# AVL

- ▷ Define balance value of a node to be the difference between height of left child and height of right child
  - NULL child is defined to have height 0!
- ▷ The tree is considered balance if every balance value is between -1 and 1
- ▷ Achieved by rotating trees

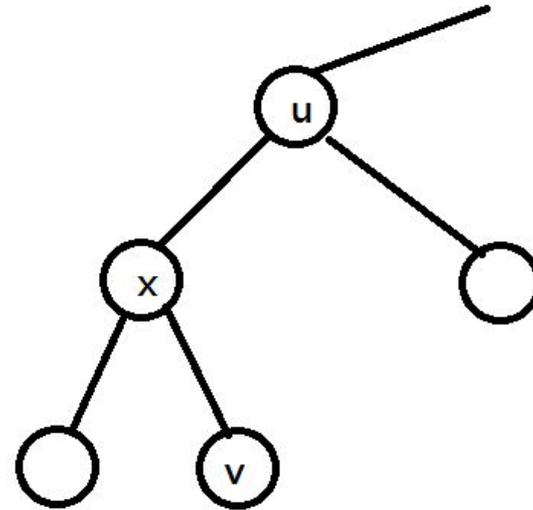

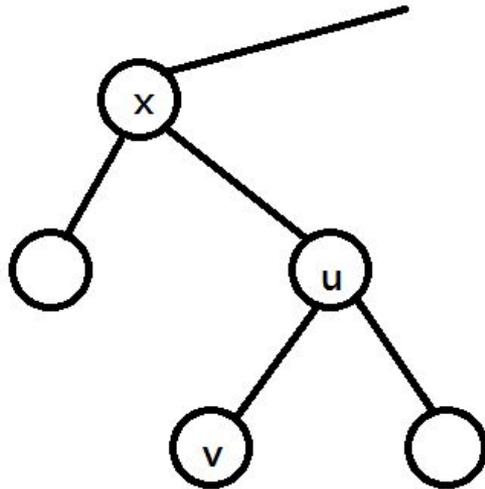

# Rotating

- ▷ A process to change the structure of tree without affecting the ordering
- ▷ Consider the right rotation on x
- ▷

# Rotating

- ▷ Similarly we can define left rotation

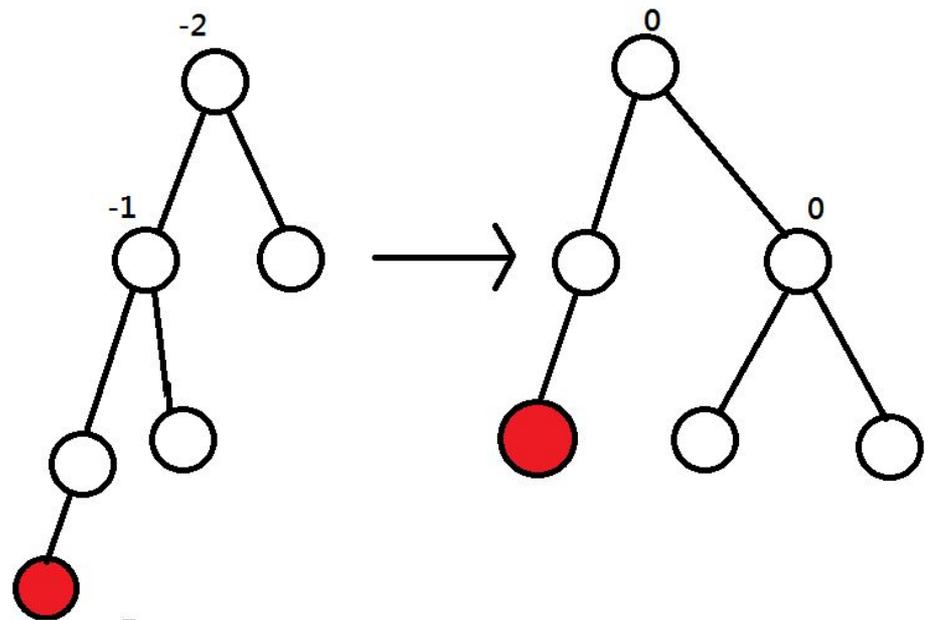

# AVL

- ▷ Consider inserting a node to a tree
- ▷ It will affect all the balance values on the path to the root
- ▷ Fix the one farthest to the root first.

# AVL

Case 1: added node at left subtree of left child

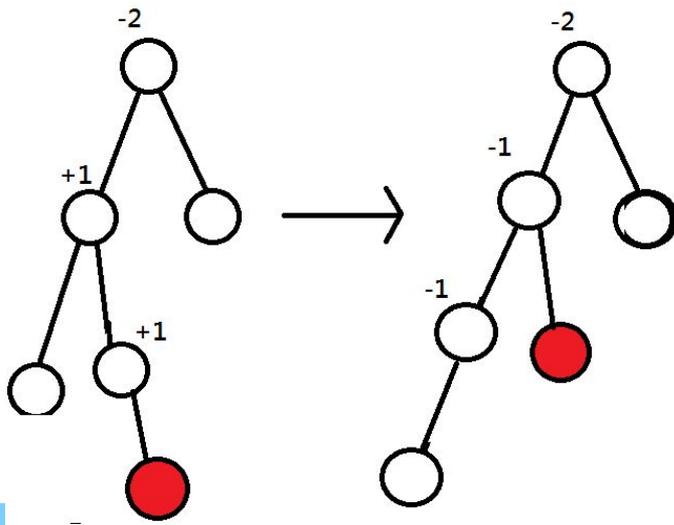

Do a right rotation and we can now fix the ancestors

# AVL

Case 2: added node at right subtree of left child

Do a left rotation **on left child**, and then a right rotation on itself and we can now fix the ancestors

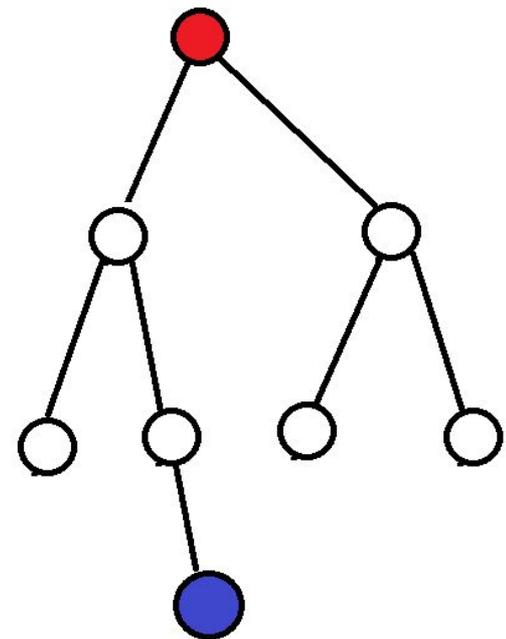

# AVL

- ▷ Case 3 and 4 (if we insert) the right child) can be solved by considering the symmetry
- ▷ What if deletion?

# AVL

- ▶ Idea: if the deleted node is not a leaf, exchange it with the immediate previous (or last) element
- ▶ Then we can treat as deleting leaves, which can be done similarly as insertion.

# AVL

- ▷ Height of tree:  $\sim O(\lg N)$
- ▷ Therefore each operation, which depends on height of tree, is in  $O(\lg N)$
- ▷ Now the tree is balanced!

# Misc

- ▷ How to recalculate balance factor
- ▷ How to get the rank of the node
- ▷ How to find immediately previous element

# Agenda

**Binary-indexed Tree (BIT)**

**Sparse Table**

**AVL tree**

**Treap**

# Treap

- ▷ Random solution to the problem
- ▷ Use the property that random binary trees are expected to be almost balanced

# Treap

- ▷ Consider giving each node a priority
- ▷ In addition to the ordered data property of the tree,
  - Priority data of the tree need to be a heap, too!

# Treap

- ▷ **Consider insertion**
  - Property may be broken
  - Solved by rotation!

# Treap

- ▷ **Idea is easy:**
  - Say the right child's priority is smaller than itself
  - We do right rotation and we check if the ancestors are good to go or not
  - Done. (already!)

# Treap

- ▷ **Consider deletion**
  - Swap with immediate previous element to make it a leaf
  - Now the swapped element violates the heap rule
  - Swap it down when appropriate
