## SUBTASKS

For all cases：
$1 \leq N \leq 2 \times 10^{5}$ ．
It is guaranteed that $H_{1 \ldots N}$ is a permutation of $1 \ldots N$ ．
Points Constraints

2 $171 \leq N \leq 50$
$3241 \leq N \leq 2000$
419
530
It is guaranteed that the bird can always escape
No additional constraints

## Solution 1 －The First Subtask

10 points for just handling two cases： $\mathbf{H}=\{\mathbf{1 , 2 \}}$ and $\mathbf{H}=\{\mathbf{2}, \mathbf{1}\}$
So we can simply＂hardcode＂them after solving them on our own

## Solution 2 －Escape

Considering only the cases that the bird can escape
It only happens iff the pillar with $\mathbf{H}=\mathbf{N}-\mathbf{1}$ is on the left of that with $\mathbf{H}=\mathbf{N}$ Thus，its y－coordinate is $\mathbf{N - 1}$ ，and the distance travelled is $\mathbf{6 \times P o s i t i o n ( \mathbf { N } ) - \mathbf { 2 }}$

## Solution 2 - Escape

## This solution can only solve Subtask 4, nothing else :)

| Subtask | Score | Max Score |

## Solution 2 －Escape

## PSEUDOCODE

```
Read(N)
For i = 1 .. N
    Read(x)
    Pos[x] = i
PrintLine('ESCAPE')
PrintLine(N - 1)
PrintLine(6 * Pos[N] - 2)
```

## Solution 3 －Simulation

We can just simply store the entire grid with a 2－d array： Marking A［i］［ $j$ ］as TRUE only if the cell（ $\mathbf{i}, \mathbf{j}$ ）is occupied by the pillars With fine implementation，the code should be able to work in $O\left(N^{2}\right)$ ， Which can pass Subtask 1,2 and 3 within time limit

## Solution 4 －Optimized Solution

We can see that if the bird cannot escape， The interval of its x－coordinate keep squeezing

We can maintain the left bound and the right bound of its x－coordinate， By updating it every time its $y$－coordinate decreases by one

## Solution 4 - Optimized Solution

In each decrement of $y$-coordinate, $O(1)$ for updating bounds
Total has $\mathbf{N}$ decrement of $\mathbf{y}$-coordinate as initial $\mathbf{y}=\mathbf{N}$
Therefore, overall time complexity is $O(N)$
Can pass the time limit for all test cases :)
