

# Optimization

Jeremy Chow 21-4-2018

# Motivation

- ❖ If you received TLE verdicts, optimizations may help you
- ❖ Every experienced competitive programmers should know
- ❖ **Usually** we don't care about constant optimizations
- ❖ Our goal is to reduce the time complexity
  - e.g. from  $O(N^2)$  to  $O(N \lg N)$  or  $O(N)$
  - e.g. from  $O(QN)$  to  $O(Q \lg N)$  or  $O(Q)$

# Optimization

- ❖ Avoid linear scans
- ❖ Avoid repeated computation
- ❖ Use memory to exchange time
- ❖ Scale down the numbers

# Agenda

- ❖ Parital sum / difference array
- ❖ Precomputation
- ❖ Sliding window (Two Pointers)
- ❖ Other techniques

# 1D Partial sum - Problem

- ❖ Given an array of integers and Q queries, for each query, find out the sum of a contiguous section of the array

1	2	3	4	5	6	7	8
2	1	0	4	2	0	1	8

$$1+0+4+2=7$$

$$4+2+0+1+8=15$$

# 1D Partial sum - Naïve solution

- ❖ For each query
- ❖ loop over the required contiguous section of the array
- ❖ add up all numbers

```
1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  int a[100005];
6
7  int main(){
8      int n, q;
9      scanf("%d%d", &n, &q);
10
11     for(int i = 1; i <= n; i++){
12         scanf("%d", &a[i]);
13     }
14
15     for(int i = 0; i < q; i++){
16         int l, r;
17         scanf("%d%d", &l, &r);
18
19         long long sum = 0;
20         for(int j = l; j <= r; j++){
21             sum += a[j];
22         }
23         printf("%lld\n", sum);
24     }
```

# 1D Partial sum - Naïve solution

- ❖ What happen when the input is like this
- ❖ For each query, you need to loop over the whole array
- ❖ Worse case time complexity :  $O(QN)$

```
n m q
a_1 a_2 ... a_n
1 n
1 n
1 n
.....
```

# 1D Partial sum - Naïve solution

- ❖ SLOW!!!!
- ❖ When  $N$  and  $Q$  are large ( $\sim 10^5$ ), you can't solve it within a second
- ❖ Need optimization
  - Avoid linear scans, precompute

# 1D Partial sum - Optimised solution

- ❖ We compute another array  $y$
- ❖ The  $i^{\text{th}}$  element = sum of the numbers in  $[1..i]$

idx	1	2	3	4	5	6	7	8
a[i]	2	1	0	4	2	0	1	8
y[i]	2	3	3	7	9	9	10	18

$$2+1+0+4+2=9$$

# 1D Partial sum - Optimised solution

- ❖ How do this array help us?
- ❖  $\text{sum in } [l..r] = \text{sum in } [1..r] - \text{sum in } [1..l-1] !$
- ❖ If we have this array  $y$ , we can compute  $\text{sum in } [l..r]$  by just visiting 2 entries

idx	1	2	3	4	5	6	7	8
a[i]	2	1	0	4	2	0	1	8
y[i]	2	3	3	7	9	9	10	18

$$9 - 2 = 7 = 1 + 0 + 4 + 2$$

# 1D Partial sum - Optimised solution

- ❖ Time complexity :  $O(Q+N)$
- ❖ Much better than  $O(QN)$
- ❖ Can pass even when N and Q is large
- ❖ Remainder : Remember to use long long when the range of elements is large (e.g.  $a_i \leq 10^9$ )

```
1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  int a[100005];
6  long long y[100005];
7
8  int main(){
9      int n, q;
10     scanf("%d%d", &n, &q);
11
12     for(int i = 1; i <= n; i++)
13         scanf("%d", &a[i]);
14
15     for(int i = 1; i <= n; i++)
16         y[i] = y[i - 1] + a[i];
17
18     for(int i = 0; i < q; i++){
19         int l, r;
20         scanf("%d%d", &l, &r);
21
22         long long sum = y[r] - y[l - 1];
23
24         printf("%lld\n", sum);
25     }
```

precompute

# 2D Partial sum - Problem

- ❖ Given a 2D array of integers and Q queries, for each query, find out the sum of a rectangular region

i \ j	1	2	3	4	5
1	4	2	6	8	2
2	3	1	9	8	3
3	5	8	0	7	0
4	4	9	6	8	4
5	2	1	0	1	2

$$6+8+2+9+8+3+0+7+0=43$$

# 2D Partial sum - Naïve solution

- ❖ For each query
- ❖ loop over the required rectangular region
- ❖ add up all numbers

```
1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  int a[1005][1005];
6
7  int main(){
8      int n, m, q;
9      scanf("%d%d%d", &n, &m, &q);
10
11     for(int i = 0; i < n; i++){
12         for(int j = 0; j < m; j++){
13             scanf("%d", a[i][j]);
14         }
15     }
16
17     for(int i = 0; i < q; i++){
18         int x, y, xx, yy;
19
20         scanf("%d%d%d%d", &x, &y, &xx, &yy);
21
22         long long sum = 0;
23         for(int j = x; j <= xx; j++){
24             for(int k = y; k <= yy; k++){
25                 sum += a[j][k];
26             }
27         }
28         printf("%lld\n", sum);
29     }
30 }
```

# 2D Partial sum - Naïve solution

- ❖ Again, when all Q queries ask for the whole array's sum
- ❖ Worst case time complexity =  $O(QNM)$
- ❖ TLE when Q, N and M = 1000
- ❖ Use idea of 1D partial sum to optimise it

# 2D Partial sum - 1D optimised solution

- ❖ For each row, we apply 1D partial sum
- ❖ For each query, we loop over the required row
- ❖ add the required interval sum for each row

# 2D Partial sum - 1D optimised solution

i \ j	1	2	3	4	5
1	4	2	6	8	2
2	3	1	9	8	3
3	5	8	0	7	0
4	4	9	6	8	4
5	2	1	0	1	2

i \ j	1	2	3	4	5
1	4	6	12	20	22
2	3	4	13	21	24
3	5	13	13	20	20
4	4	13	19	27	31
5	2	3	3	4	6

$$(22-6)+(24-4)+(20-13)=43$$

# 2D Partial sum - 1D optimised solution

- ❖ Time complexity :  $O(QN)$  or  $O(Q\min(N,M))$
- ❖ Improved
- ❖ Can we do it better?

# 2D Partial sum - Solution

- ❖ In 1D version,  $\text{sum in } [l..r] = \text{sum in } [1..r] - \text{sum in } [1..l-1]$
- ❖ Can we get some similar formula in 2D version?

# 2D Partial sum - Solution

❖  $\text{Magenta} = \text{Yellow} - \text{Red} - \text{Blue} + \text{Green}$

❖  $\text{sum in } [x1..x2][y1..y2] = \text{sum in } [1..x2][1..y2] -$

$\text{sum in } [1..x1-1][1..y2] - \text{sum in } [1..x2][1..y1-1] -$

$\text{sum in } [1..x1-1][1..y1-1]$

# 2D Partial sum - Solution

- ❖ Compute another array  $s$
- ❖  $s[i][j] = \text{sum in } [1..i, 1..j]$ 
  - $= a[i][j] + s[i-1][j] + s[i][j-1] - s[i-1][j-1];$
- ❖  $\text{Ans} = s[x2][y2] - s[x2][y1-1] - s[x1-1][y2] + s[x1-1][y1-1]$

# 2D Partial sum - Solution

- ❖ Time complexity =  $O(Q+NM)$
- ❖ Partial sum always appear in  $OI$
- ❖ Need to be able to code it

```
int n, m, q;
scanf("%d%d%d", &n, &m, &q);

for(int i = 1; i <= n; i++){
    for(int j = 1; j <= m; j++){
        scanf("%d", &a[i][j]);
    }

    for(int i = 1; i <= n; i++){
        for(int j = 1; j <= m; j++){
            s[i][j] = a[i][j] + s[i - 1][j] + s[i][j - 1] - s[i - 1][j - 1];
        }
    }

    for(int i = 0; i < q; i++){
        int x1, y1, x2, y2;

        scanf("%d%d%d%d", &x1, &y1, &x2, &y2);

        long long sum = s[x2][y2] - s[x2][y1 - 1] - s[x1 - 1][y2] + s[x1 - 1][y1 - 1];

        printf("%lld\n", sum);
    }
}
```

# 1D Difference array - Problem

- ❖ There are Q queries, each query add  $v_i$  to the contiguous section of the array, find the final value of the array
- ❖ ADD 3 to [2..5]

idx	1	2	3	4	5
a_i	0	3	3	3	3

- ❖ ADD 4 to [1..3]

idx	1	2	3	4	5
a_i	4	7	7	3	3

# 1D Difference array - Naïve solution

- ❖ For each query, loop that contiguous section
- ❖ add  $v_i$  to them
- ❖ Time complexity  $O(QN)$
- ❖ Can we do better?

```
1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  int a[100005]
6  long long s[1005][1005];
7
8  int main(){
9      int n, m, q;
10     scanf("%d%d", &n, &q);
11
12     for(int i = 1; i <= n; i++)
13         scanf("%d", &a[i]);
14
15     for(int i = 0; i < q; i++){
16         int l, r, v;
17         scanf("%d%d%d", &l, &r, &v);
18         for(int j = l; j <= r; j++)
19             a[j] += v;
20     }
```

# 1D Difference array - Solution

- ❖ Define a new array  $d$
- ❖  $d[i] = a[i] - a[i - 1]$
- ❖ If we can find array  $d$ , we can get array  $a$  easily by  $a[i] = d[i] + a[i - 1]$

idx	1	2	3	4	5
a_i	4	7	7	3	3

idx	1	2	3	4	5
d_i	4	3	0	-4	0

# 1D Difference array - Solution

- ❖ Imagine what happen when we add  $v_i$  on the contiguous section  $[l..r]$
- ❖ The difference between  $a[l]$  and  $a[l - 1]$  will  $+ v_i$
- ❖ The difference between  $a[r+1]$  and  $a[r]$  will  $- v_i$
- ❖ We only need to update 2 values ( $d[l]$  and  $d[r+1]$ ) instead of  $(l-r+1)$  values

# 1D Difference array - Solution

- ❖ Time complexity =  $O(N + Q)$
- ❖ Way better than  $O(NQ)$
- ❖ Frequently used technique

```
1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  int a[100005]
6  long long d[100005];
7
8  int main(){
9      int n, m, q;
10     scanf("%d%d", &n, &q);
11
12     for(int i = 1; i <= n; i++)
13         scanf("%d", &a[i]);
14
15     for(int i = 0; i < q; i++){
16         int l, r, v;
17         scanf("%d%d%d", &l, &r, &v);
18         d[l] += v;
19         d[r + 1] -= v;
20     }
21
22     for(int i = 1; i <= n; i++)
23         a[i] = a[i - 1] + d[i];
24
```

# 2D Difference array - Problem

- ❖ There are  $Q$  queries, each query add  $v_i$  to the rectangular region of the matrix, find the final value of the matrix
- ❖ Same as partial sum, difference array can be applied to 2D too
- ❖ Naïve solution works in  $O(QNM)$
- ❖ ADD 5 to  $[1..3, 1..3]$

0	0	0	0	0
0	5	5	5	0
0	5	5	5	0
0	5	5	5	0
0	0	0	0	0

# 2D Difference array - Solution

- ❖ Define a new array  $d$
- ❖  $d[i][j] = a[i][j] - a[i][j - 1] - a[i - 1][j] + a[i - 1][j - 1]$
- ❖ Imagine what happen when we add  $v$  on the rectangular region  $[l1..l2, r1..r2]$
- ❖  $d[l1][r1] += v$ ,  $d[l1][r2 + 1] -= v$ ,  $d[l2 + 1][r1] -= v$ ,  $d[l2 + 1][r2 + 1] += v$ ;
- ❖ We only need to update 4 value per query

# 2D Difference array - Solution

❖ After getting array d, we can get array a easily by

➤  $a[i][j] = a[i - 1][j] + a[i][j - 1] - a[i - 1][j - 1] + d[i][j]$

5	0	0	-5	0
0	0	0	0	0
0	0	0	0	0
-5	0	0	5	0
0	0	0	0	0

0	0	0	0	0
0	5	5	5	0
0	5	5	5	0
0	5	5	5	0
0	0	0	0	0

# 2D Difference array - Solution

❖ Time complexity =  $O(NM + Q)$

```
1 #include <bits/stdc++.h>
2
3 using namespace std;
4
5 int a[1005][1005];
6 long long d[1005][1005];
7
8 int main(){
9     int n, m, q;
10    scanf("%d%d%d", &n, &m, &q);
11
12    for(int i = 1; i <= n; i++){
13        for(int j = 1; j <= m; j++){
14            scanf("%d", &a[i][j]);
15        }
16    }
17
18    for(int i = 0; i < q; i++){
19        int l1, r1, l2, r2, v;
20        scanf("%d%d%d%d%d", &l1, &r1, &l2, &r2, &v);
21
22        d[l1][r1] += v, d[l1][r2 + 1] -= v, d[l2 + 1][r1] -= v, d[l2 + 1][r2 + 1] += v;
23    }
24
25    for(int i = 1; i <= n; i++){
26        for(int j = 1; j <= m; j++){
27            a[i][j] = a[i - 1][j] + a[i][j - 1] - a[i - 1][j - 1] + d[i][j];
28        }
29    }
30
31    for(int i = 1; i <= n; i++){
32        for(int j = 1; j <= m; j++){
33            printf(" %d", a[i][j]);
34            printf("\n");
35        }
36    }
```

# Precomputation - Problem

- ❖ Given a string consists of 'A' and 'B' and Q queries, for each query  $q_i$ , you need to find the closest "B" which index is  $\leq q_i$
- ❖ AABAAABBA
- ❖ Q 3 -> 3
- ❖ Q 9 -> 8

# Precomputation - Naïve solution

- ❖ For each query, loop over all the index  $\leq q_i$
- ❖ Time complexity =  $O(QN)$
- ❖ With the help of precomputation, we can improve it !

# Precomputation - Solution

- ❖ Build an array  $lt$ , which  $lt[i]$  means the last "B" which index  $\leq i$
- ❖ AABAAABBA

idx	1	2	3	4	5	6	7	8	9
lt_i	-1	-1	3	3	3	3	7	8	8

# Precomputation - Solution

- ❖ You can build that array easily in  $O(N)$
- ❖ For each query, you just need to print the precomputed  $It[qi]$
- ❖ Time complexity =  $O(Q+N)$

# Precomputation - Solution

- ❖ useful array to be precomputed
  - Prefix / suffix sum (partial sum)
  - Prefix / suffix max / min
  - Prefix / suffix xor sum
  - Prefix / suffix count
    - number of odd numbers
    - number of “\*”
    - index of last special element

# Two pointers - Problem

- ❖ Given two sorted array of integers  $a$  and  $b$ , find the number of pair  $(i, j)$  such that

$$a_i + b_j = C$$

<b>1</b>	<b>5</b>	<b>8</b>	<b>10</b>	<b>12</b>	<b>14</b>	<b>15</b>	<b>18</b>	<b>25</b>
<b>3</b>	<b>6</b>	<b>6</b>	<b>7</b>	<b>13</b>	<b>14</b>	<b>15</b>	<b>18</b>	<b>19</b>

- ❖ when  $C = 20$

- ❖ ANS = 3  $\{(1, 9), (2, 7), (6, 3)\}$

# Two pointers - Naïve solution

- ❖ For each element in a, loop over array b
- ❖ count how many  $a_i + b_j = C$
- ❖ Time complexity =  $O(N^2)$
- ❖ Hint : **Sorted** array

# Two pointers - Binary search solution

- ❖ For each element in a, binary search the count of numbers

such that  $b_j = C - a_i$

- ❖ Need two binary search if the numbers are not distinct
- ❖ However, we can improve it more

# Two pointers - Solution

- ❖ Just like binary search, two pointers can improve the algorithm by avoiding impossible case
- ❖ Also, it avoid repeated checking.

# Two pointers - Solution

- ❖ Notice array a and b is **sorted**, let's assume we are loop the array a
- ❖ For each  $a_i$ , our target is the elements in b equal to  $C - a_i$
- ❖ When i grow,  $a_i$  is increasing, so our target  $C - a_i$  is decreasing
- ❖ For the number larger than  $C - a_i$ , we don't need to consider it in  $i + 1, i + 2, \dots, n$
- ❖ Avoid impossible case

# Two pointers - Solution

1	5	8	10	12	14	14	18	25
3	5	6	7	13	14	15	18	19

1	5	8	10	12	14	14	18	25
3	5	6	7	13	14	15	18	19

1	5	8	10	12	14	14	18	25
3	6	6	7	13	14	15	18	19

1	5	8	10	12	14	14	18	25
3	6	6	7	13	14	15	18	19

1	5	8	10	12	14	14	18	25
3	6	6	7	13	14	15	18	19

# Two pointers - Solution

- ❖ As both pointers traverse the array once
- ❖ Time complexity =  $O(N)$
- ❖ We usually use while loop to implement
- ❖ Easy to code

```
1  int j = n - 1;
2  int res = 0;
3
4  for(int i = 0; i < n; i++){
5      while(j >= 0 && b[j] > c - a[i])
6          j--;
7
8      if(j >= 0 && a[i] + b[j] == c)
9          res++;
10 }
11
```

Assist pointer

Main pointer

# Two pointers - When to use

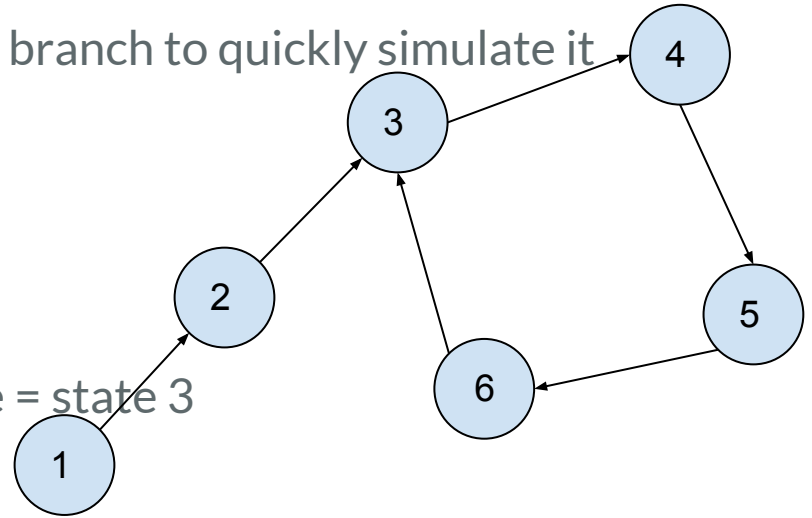

- ❖ On sorted array
- ❖ Things we want to find have monotonicity
- ❖ e.g. sum, count of sth etc.

# Other techniques - finding cycles

- ❖ In some simulation problems, we may need to simulate  $N$  steps
- ❖ However,  $N$  is really large (e.g.  $\sim 10^{18}$ )
- ❖ TLE if you do  $O(N)$  simulate

# Other techniques - finding cycles

- ❖ Usually in this type of problems, some state will form a cycle
- ❖ You need to find out the cycle and the branch to quickly simulate it
- ❖ branch = 2, cycle = 4
- ❖ E.g. walk 98 steps from 1
- ❖ ANS =  $((98 - 2) \% 4)^{\text{th}}$  state in the cycle = state 3
- ❖ Time complexity =  $O(\text{no. of state})$

# Other techniques - discretization

- ❖ Discretization (離散法) is a technique that converts values (not necessarily integers) into integers, while maintaining their relative order
- ❖ Example: 7654321, 123456, 934602, 123456789  
-> 3, 1, 2, 4 (or 2, 0, 1, 3)
- ❖ Put the values into an array, sort the array
  - 123456, 934602, 7654321, 123456789
- ❖ For each value in the original array, find its rank using binary search

# Other techniques - discretization

- ❖ Discretize large numbers into smaller numbers
- ❖ Handle data easily
- ❖ E.g count the number of occurrence of some numbers in array a
- ❖  $a_i \leq 10^9$
- ❖ Counting with array after discretization

# Other techniques - discretization

- ❖ 座標壓縮
- ❖ useful when the coordinates are large
- ❖ can perform dfs / bfs on the compressed grid
  - e.g. find the number of connected component

# Other techniques - discretization

# Q&A
